Incorporating unobserved heterogeneity in Weibull survival models: A Bayesian approach

Catalina Vallejos  Mark F.J. Steel

Department of Statistics, University of Warwick

Wirtschaftsuniversität Wien, May 14, 2014
Parametric survival models such as the Weibull or log-normal

- Do not allow **unobserved heterogeneity** between observations,

- Do not produce robust inference under the presence of outliers.
Motivation

Parametric survival models such as the Weibull or log-normal

- Do not allow *unobserved heterogeneity* between observations,

- Do not produce robust inference under the presence of outliers.
Mixtures of life distributions

Definition

The distribution of $T_i$ is defined as a mixture of life distributions, if and only if its density function is given by

$$f(t_i | \psi, \theta) \equiv \int_{\mathcal{L}} f^*(t_i | \psi, \Lambda_i = \lambda_i) dP_{\Lambda_i}(\lambda_i | \theta),$$

where $f^*(\cdot | \psi, \Lambda_i = \lambda_i)$ is the density of a lifetime distribution and $P_{\Lambda_i}(\cdot | \theta)$ is a distribution function on $\mathcal{L}$ possibly depending on a parameter $\theta \in \Theta$. 
Mixtures of life distributions

- **Unobserved heterogeneity** is incorporated via $\lambda_i$ (frailty),
- The influence of **outlying observations** is attenuated,
- **Flexible** distributions are generated on the basis of well-known distributions,
- The **intuition** behind the underlying model is preserved.
Mixtures of life distributions

- **Unobserved heterogeneity** is incorporated via $\lambda_i$ (frailty),

- The influence of **outlying observations** is attenuated,

- **Flexible** distributions are generated on the basis of well-known distributions,

- The **intuition** behind the underlying model is preserved.
Mixtures of life distributions

- **Unobserved heterogeneity** is incorporated via $\lambda_i$ (frailty),

- The influence of **outlying observations** is attenuated,

- The influence of outlying observations is attenuated,

- Flexible distributions are generated on the basis of well-known distributions,

- The intuition behind the underlying model is preserved.
Definition

A random variable $T_i$ has distribution in the family of Rate Mixtures of Weibull distributions (RMW) iff

$$f(t_i|\alpha, \gamma, \theta) = \int_{\mathcal{L}} \gamma \alpha \lambda_i e^{-\alpha \lambda_i t_i^\gamma} t_i^{\gamma-1} dP_{\Lambda_i}(\lambda_i|\theta), \quad t_i > 0, \alpha, \gamma > 0, \theta \in \Theta,$$

with $P_{\Lambda_i}(\cdot|\theta)$ defined on $\mathcal{L} \subseteq (0, \infty)$ (possibly discrete). Denote $T_i \sim \text{RMW}_P(\alpha, \gamma, \theta)$. Alternatively, (1) can be expressed as the hierarchical representation

$$T_i|\alpha, \gamma, \Lambda_i = \lambda_i \sim \text{Weibull} (\alpha \lambda_i, \gamma), \quad \Lambda_i|\theta \sim P_{\Lambda_i}(\cdot|\theta).$$

(2)
Rate Mixtures of Weibull distributions

- Relates to existing literature, where usually $\gamma = 1$ and mixing distribution is gamma (Lomax distribution)
- Case $\gamma = 1$: Rate Mixtures of Exponentials $T_i \sim \text{RME}_P(\alpha, \theta)$
- RMW and RME linked by simple power transformation
  - If $T_i \sim \text{RME}_P(\alpha, \theta)$ then $T_i^{1/\gamma} \sim \text{RMW}_P(\alpha, \gamma, \theta)$.
- For $\gamma \leq 1$: decreasing hazard rate for any $P$
- For $\gamma > 1$: hazard rate can be non-monotone
- Identifiability precludes separate unknown scale parameters in $P$
Rate Mixtures of Weibull distributions

- Relates to existing literature, where usually $\gamma = 1$ and mixing distribution is gamma (Lomax distribution)

- Case $\gamma = 1$: Rate Mixtures of Exponentials
  $T_i \sim \text{RME}_P(\alpha, \theta)$

  - RMW and RME linked by simple power transformation
    If $T_i \sim \text{RME}_P(\alpha, \theta)$ then $T_i^{1/\gamma} \sim \text{RMW}_P(\alpha, \gamma, \theta)$.

- For $\gamma \leq 1$: decreasing hazard rate for any $P$

- For $\gamma > 1$: hazard rate can be non-monotone

- Identifiability precludes separate unknown scale parameters in $P$
Rate Mixtures of Weibull distributions

- Relates to existing literature, where usually $\gamma = 1$ and mixing distribution is gamma (Lomax distribution).

Some examples of RMW

**Figure**: Some RMW models ($\alpha = 1$). The mixing distribution is Gamma($\theta, \theta$) (Exponential(1) for $\theta = 1$). The solid line is the Weibull(1, $\gamma$) density and hazard function.
If all the required moments exist, the coefficient of variation \( (cv) \) of the survival distributions in (1) is

\[
\text{cv}(\gamma, \theta) = \sqrt{\frac{\Gamma (1 + 2/\gamma)}{\Gamma^2 (1 + 1/\gamma)} \frac{\text{var}_{\Lambda_i}(\Lambda_i^{-1/\gamma}|\theta)}{E_{\Lambda_i}^2(\Lambda_i^{-1/\gamma}|\theta)}} + \frac{\left[ \Gamma (1 + 2/\gamma) - \Gamma^2 (1 + 1/\gamma) \right]}{\Gamma^2 (1 + 1/\gamma)} (cv^*(\gamma, \theta))^2 + (cv^W(\gamma))^2.
\]

Simplifies to

\[
\sqrt{2 \frac{\text{var}_{\Lambda_i}(\Lambda_i^{-1}|\theta)}{E_{\Lambda_i}^2(\Lambda_i^{-1}|\theta)}} + 1 \text{ when } \gamma = 1.
\]

We restrict the range of \((\gamma, \theta)\) such that \(cv\) is finite (not required when \(\theta\) does not appear).
Coefficient of variation inflation

- cv of the Weibull $cv^W(\gamma)$ is a lower bound for $cv(\gamma, \theta)$
- $cv(\gamma, \theta) = cv^W(\gamma)$ iff $\Lambda_i = \lambda_0$ with probability 1.
- Evidence of unobserved heterogeneity:

$$R_{cv}(\gamma, \theta) = \frac{cv(\gamma, \theta)}{cv^W(\gamma)},$$

i.e. the cv inflation that the mixture induces (w.r.t. Weibull with the same $\gamma$).
- If $\gamma \to 0$, $cv^W(\gamma)$ and, thus, $cv(\gamma, \theta)$ become unbounded. Then $R_{cv}(\gamma, \theta)$ behaves as $\sqrt{[cv^*(\gamma, \theta)]^2 + 1}$. 

Coefficient of variation inflation

- cv of the Weibull $cv^W(\gamma)$ is a lower bound for $cv(\gamma, \theta)$
- $cv(\gamma, \theta) = cv^W(\gamma)$ iff $\Lambda_i = \lambda_0$ with probability 1.
- Evidence of unobserved heterogeneity:

$$R_{cv}(\gamma, \theta) = \frac{cv(\gamma, \theta)}{cv^W(\gamma)},$$

i.e. the cv inflation that the mixture induces (w.r.t. Weibull with the same $\gamma$).
- If $\gamma \to 0$, $cv^W(\gamma)$ and, thus, $cv(\gamma, \theta)$ become unbounded. Then $R_{cv}(\gamma, \theta)$ behaves as $\sqrt{[cv^*(\gamma, \theta)]^2 + 1}$. 
Coefficient of variation inflation

- \(cv\) of the Weibull \(cv^W(\gamma)\) is a lower bound for \(cv(\gamma, \theta)\).
- \(cv(\gamma, \theta) = cv^W(\gamma)\) iff \(\Lambda_i = \lambda_0\) with probability 1.
- Evidence of unobserved heterogeneity:

\[
R_{cv}(\gamma, \theta) = \frac{cv(\gamma, \theta)}{cv^W(\gamma)},
\]

i.e. the \(cv\) inflation that the mixture induces (w.r.t. Weibull with the same \(\gamma\)).

- If \(\gamma \to 0\), \(cv^W(\gamma)\) and, thus, \(cv(\gamma, \theta)\) become unbounded. Then \(R_{cv}(\gamma, \theta)\) behaves as \(\sqrt{[cv^*(\gamma, \theta)]^2 + 1}\).
Coefficient of variation inflation

- cv of the Weibull $cv^W(\gamma)$ is a lower bound for $cv(\gamma, \theta)$
- $cv(\gamma, \theta) = cv^W(\gamma)$ iff $\Lambda_i = \lambda_0$ with probability 1.
- Evidence of unobserved heterogeneity:

i.e. the cv inflation that the mixture induces (w.r.t. Weibull with the same $\gamma$).

- If $\gamma \rightarrow 0$, $cv^W(\gamma)$ and, thus, $cv(\gamma, \theta)$ become unbounded. Then $R_{cv}(\gamma, \theta)$ behaves as $\sqrt{[cv^*(\gamma, \theta)]^2 + 1}$. 
Regression Model

Weibull regression model can equivalently be written in terms of Accelerated Failure Times (AFT) and Proportional Hazard (PH) specifications

AFT-RMW (covariates affect the time scale through $\alpha$):

$$T_i \sim RMW_p(\alpha_i, \gamma, \theta), \quad \alpha_i = e^{-\gamma x_i' \beta}, \quad i = 1, \ldots, n,$$

or

$$\log(T_i) = x_i' \beta + \log(\Lambda_i T_0),$$

where $\Lambda_i \sim dP_{\Lambda_i}(\theta)$ and $T_0 \sim \text{Weibull}(1, \gamma)$.

- AFT-RMW is itself an AFT model
- $e^{\beta_j}$ can be interpreted as the proportional change of the median survival time after a unit change in covariate $j$
- PH-RMW model is not PH model, and interpretation of coefficients is less clear
Regression Model

Weibull regression model can equivalently be written in terms of Accelerated Failure Times (AFT) and Proportional Hazard (PH) specifications.

AFT-RMW (covariates affect the time scale through $\alpha$):

$$T_i \sim RMW_{\alpha_i}(\gamma, \theta), \quad \alpha_i = e^{-\gamma x_i' \beta}, \quad i = 1, \ldots, n, \quad (5)$$

or

$$\log(T_i) = x_i' \beta + \log(\Lambda_i T_0), \quad (6)$$

where $\Lambda_i \sim dP_{\Lambda_i}(\theta)$ and $T_0 \sim \text{Weibull}(1, \gamma)$.

- AFT-RMW is itself an AFT model.
- $e^{\beta_j}$ can be interpreted as the proportional change of the median survival time after a unit change in covariate $j$.
- PH-RMW model is not PH model, and interpretation of coefficients is less clear.

Bayesian inference for the AFT-RMW model

Prior

First consider RME ($\gamma = 1$)
Jeffreys and independence Jeffreys priors have structure

$$\pi(\beta, \theta) \propto \pi(\theta),$$

(7)

but they are complicated to derive and $\pi(\theta)$ need not be proper (no comparison through BF).

Approach:
- Keep structure in (7), but use a proper $\pi(\theta)$
- Match priors through common proper prior for $\alpha$, say $\pi^*(\alpha)$
- Using (3), derive the functional relationship between $\alpha$ and $\theta$; Table does this for some RME distributions
Bayesian inference for the AFT-RMW model

Prior

First consider RME ($\gamma = 1$)
Jeffreys and independence Jeffreys priors have structure

$$\pi(\beta, \theta) \propto \pi(\theta), \quad (7)$$

but they are complicated to derive and $\pi(\theta)$ need not be proper (no comparison through BF).

Approach:
- Keep structure in (7), but use a proper $\pi(\theta)$
- Match priors through common proper prior for $cv$, say $\pi^*(cv)$
- Using (3), derive the functional relationship between $cv$ and $\theta$. Table does this for some RME distributions

Posterior

- Improper prior: need to check propriety of posterior
- Some observations may be censored

Adding censored observations can not destroy posterior existence, so consider only non-censored ones for sufficient conditions:

Let $T_1, \ldots, T_n$ be the survival times of $n$ independent individuals distributed as in (5). Define $X = (x_1, \ldots, x_n)$. Suppose $n \geq k$, $r(X) = k$ (full rank) and that the prior is proportional to $\pi(\gamma, \theta)$, which is proper for $(\gamma, \theta)$. If $t_i > 0$ for all $i = 1, \ldots, n$, the posterior distribution of $(\beta, \gamma, \theta)$ is proper.

Bayesian inference for the AFT-RMW model

Outliers

- Outliers: extreme $\lambda_i$
- Effect of outliers on posterior of $\beta$ is attenuated by mixing
- Identification of outliers through mixing variables: compare $H_0 : \Lambda_i = \lambda_{ref}$ with $H_1 : \Lambda_i \neq \lambda_{ref}$ (with all other $\Lambda_j, j \neq i$ free)
- BF can be computed by generalized Savage-Dickey density ratio

$$BF_{01}^{(i)} = \pi(\lambda_i|t, c)E\left(\frac{1}{dP(\lambda_i|\theta)}\right)|_{\lambda_i=\lambda_{ref}}$$

(computationally intensive, but simplifies to SD density ratio when no $\theta$). Choice of $\lambda_{ref}$? 
Outliers: extreme $\lambda_i$

Effect of outliers on posterior of $\beta$ is attenuated by mixing

Identification of outliers through mixing variables: compare $H_0: \Lambda_i = \lambda_{\text{ref}}$ with $H_1: \Lambda_i \neq \lambda_{\text{ref}}$ (with all other $\Lambda_j, j \neq i$ free)

BF can be computed by generalized Savage-Dickey density ratio

$$BF_{01}^{(i)} = \pi(\lambda_i|t,c)E\left(\frac{1}{dP(\lambda_i|\theta)}\right)|_{\lambda_i = \lambda_{\text{ref}}}$$

(computationally intensive, but simplifies to SD density ratio when no $\theta$). Choice of $\lambda_{\text{ref}}$?
Bayesian inference for the AFT-RMW model

Outliers

- Outliers: extreme $\lambda_i$
- Effect of outliers on posterior of $\beta$ is attenuated by mixing
- Identification of outliers through mixing variables: compare $H_0 : \Lambda_i = \lambda_{ref}$ with $H_1 : \Lambda_i \neq \lambda_{ref}$ (with all other $\Lambda_j, j \neq i$ free)

BF can be computed by generalized Savage-Dickey density ratio

$$BF^{(i)}_{01} = \pi(\lambda_i|t, c)E\left(\frac{1}{dP(\lambda_i|\theta)}\right)\bigg|_{\lambda_i=\lambda_{ref}}$$

(computationally intensive, but simplifies to SD density ratio when no $\theta$). Choice of $\lambda_{ref}$?
Use $\lambda_{\text{ref}} = E(\Lambda_i|\theta)$, replacing $\theta$ by its posterior median

Mixing through scale parameter, so censoring very informative for mixing parameters. So for censored observations we use correction factor:

$$\lambda_{\text{ref}}^c = R_i(\beta, \gamma, \theta)\lambda_{\text{ref}}^o,$$

with

$$R_i(\beta, \gamma, \theta) = \frac{E(\Lambda_i|t_i, c_i = 0, \beta, \gamma, \theta)}{E(\Lambda_i|t_i, c_i = 1, \beta, \gamma, \theta)}.$$
Use $\lambda_{ref} = E(\Lambda_i|\theta)$, replacing $\theta$ by its posterior median.

Mixing through scale parameter, so censoring very informative for mixing parameters. So for censored observations we use correction factor:

$$
\lambda^c_{ref} = R_i(\beta, \gamma, \theta)\lambda^o_{ref}, \text{ with } R_i(\beta, \gamma, \theta) = \frac{E(\Lambda_i|t_i, c_i = 0, \beta, \gamma, \theta)}{E(\Lambda_i|t_i, c_i = 1, \beta, \gamma, \theta)}.
$$
Application to cerebral palsy data

1,549 children affected by cerebral palsy, born 1966-1984 in Mersey region. Record survival times in years. Covariates: amount of severe impairments, birth weight. Only 242 recorded deaths, so 84.4% is right censored.

Analysed with AFT-RMW model as well as a Weibull model. Inference on $\beta$ (see graph) is similar for most mixture distributions, but different from Weibull in $\beta_1$ (effect of no impairment).

Inference on $\gamma$ clearly suggests $\gamma > 1$ (non-monotone hazard rate). Larger $\gamma$ for mixture models (Weibull underestimates $\gamma$ to accommodate data variability).

Posterior results for cerebral palsy data

**Figure:** 95% HPD intervals and posterior medians. Model (5) and (8) with Gamma prior for \( \gamma \) and Trunc-Exp or Pareto prior for \( cv \). From left to right: Gamma(4,1), Gamma(1,1) and Gamma(0.01,0.01) prior for \( \gamma \). Values of E(\(cv\)) in top panel. \( \beta_0 \): intercept, \( \beta_1 \): no impairments.
Model comparison for cerebral palsy data

Figure: Cerebral palsy dataset. Model comparison in terms of BF and PsML. Unfilled and filled characters denote a truncated exponential and Pareto prior for $cv$. Upper panels use $E(cv) = 1.5$. Lower panels use $E(cv) = 5$. 
Outlier detection for cerebral palsy data

Figure: Cerebral palsy dataset using the exponential mixing distribution. BF in favour of the hypothesis $\lambda_i \neq \lambda_{ref}$, with $\lambda_{ref}^o = 1$ and $\lambda_{ref}^c = 1/2$

No individual outliers, but strong support for mixing. Corroborated by inference on $R_{cv}$ (posterior median around 2).
Conclusions

1. Propose mixtures of life distributions (rate mixtures of Weibulls) to deal with unobserved heterogeneity and outliers
2. Obtain flexible classes in shape and tails
3. Covariates through AFT specification: retains AFT and $\beta$ interpretable
4. Prior based on structure of Jeffreys prior, but allows meaningful BFs
5. Derive simple conditions for posterior existence
6. Outlier detection based on mixing parameters
7. Data support mixing; in particular exponential mixing distribution (easy to elicit and to implement, as no $\theta$)
Conclusions

1. Propose mixtures of life distributions (rate mixtures of Weibulls) to deal with unobserved heterogeneity and outliers.
2. Obtain flexible classes in shape and tails.
3. Covariates through AFT specification: retains AFT and $\beta$ interpretable.
4. Prior based on structure of Jeffreys prior, but allows meaningful BF.
5. Derive simple conditions for posterior existence.
6. Outlier detection based on mixing parameters.
