Einleitung

Die vorliegende Bevölkerungsprognose bis 2050 sowie Modellrechnung bis 2075 für Österreich und die Bundesländer basiert auf dem Bevölkerungsstand vom 1. Jänner 2007. Die Annahmen zu Mortalität und Migration wurden für diese neue Prognosegeneration im Rahmen von Arbeitsgruppen mit Fachleuten aus Wissenschaft und Verwaltung neu überarbeitet. Die Langfristannahmen zur Fertilität wurden auf Österreichebene im Wesentlichen unverändert aus der letzten Prognose übernommen. Gerechnet wurde die Vorausschätzung mit dem vom Deutschen KOSIS-Verbund entwickelten PC-Programm SIKURS v8.3. Es handelt sich dabei um ein multiregionales Bevölkerungsprognosemodell.

Der vorliegende Schnellbericht besteht aus 10 Bänden (je ein Heft für Österreich und jedes Bundesland) und beinhaltet die Ergebnisse der mittleren Variante der Bevölkerungsvorausschätzung bis zum Jahr 2050, die auch als Hauptvariante der Prognose gilt. Eine modellhafte Fortführung der Berechnungen unter völliger Konstanz aller Prognoseparameter bis zum Jahr 2075 ermöglicht auch einen demographischen Blick in die 2. Hälfte des 21. Jahrhunderts. Das Hauptszenario basiert auf der Kombination der mittleren Fertilitäts-, Mortalitäts- und Migrationsannahmen. Die einzelnen Parameter der Vorausschätzung (Fertilitätsraten, Lebenserwartung, internationale Zu- und Abwanderung sowie Binnenwanderungsströme) sind in den Tabellen 1 und 2 angeführt. Ausführlich beschrieben wird die Bevölkerungsprognose in den Statistischen Nachrichten, Heft 12/2007 sowie überblicksmäßig auch im Demographischen Jahrbuch 2006.

Die Tabellen liegen auch im EXCEL-Format vor und auf der Homepage der STATISTIK AUSTRIA publiziert.

Erläuterung der Maßzahlen und Indikatoren

Allgemeine Fruchtbarkeitsziffer (AFZ): Lebendgeborene insgesamt auf 1.000 Frauen von 15 bis unter 45 Jahren.

Belastungsquoten: Auf 100 Personen im Alter von 15 bis unter 60 Jahren entfallen ... Personen im Alter von unter 15 Jahren (**Kinder**), über 60 Jahren (**Alte**), unter 15 Jahren sowie über 60 Jahren (**Gesamt**).

Bruttoreproduktionsrate (BRR): Sie gibt an, wie viele lebendgeborene Töchter eine Frau zur Welt bringen würde, wenn im Laufe ihres Lebens dieselben altersspezifischen Fertilitätsverhältnisse herrschen würden wie in dem betreffenden Kalenderjahr (und wenn von der Sterblichkeit der Frau abgesehen würde). Sie unterscheidet sich von der Gesamtfertilitätsrate (GFR) dadurch, dass hier lediglich die Mädchengeburten berücksichtigt werden. Berechnet wird sie als Summe der Quotienten aus den weiblichen Lebendgeborenen nach einjährigen Altersgruppen der Mütter und den Frauen gleichen Alters. (Berechnet mit einer konstanten Sexualproportion von 1.057 Knaben auf 1.000 Mädchen.)

Durchschnittliches Fruchtbarkeitsalter (DFA): Arithmetisches Mittel der Altersverteilung der Fertilitätsziffern für einjährige Altersgruppen.

Geburten- bzw. Sterbeziffer (roh): Lebendgeborene bzw. Gestorbene, jeweils bezogen auf 1.000 Einwohner.

Geburtenbilanzziffer: Geburtenüberschuss bzw. -defizit auf 1.000 Einwohner.

Gesamtfertilitätsrate (GFR): Die Gesamtfertilitätsrate eines Kalenderjahres gibt an, wie viele lebendgeborene Kinder eine Frau zur Welt bringen würde, wenn im Laufe ihres Lebens dieselben altersspezifischen Fertilitätsverhältnisse herrschen würden wie in dem betreffenden Kalenderjahr (und wenn von der Sterblichkeit der Frau abgesehen würde). Sie eignet sich als Prognosewert für die endgültige Kinderzahl einer am Beginn des gebärfähigen Alters stehenden Frau nur dann, wenn in den nachfolgenden Kalenderjahren die altersspezifischen Fertilitätsziffern unverändert bleiben. In erster Linie stellt sie einen zusammenfassenden Indikator der altersspezifischen Fertilitätsziffern eines Kalenderjahres dar, womit sie eine ähnliche Funktion erfüllt wie die Lebenserwartung auf dem Gebiet der Sterblichkeit (altersstandardisierter Fertilitätsindex, bei dem die altersspezifischen Fertilitätsziffern

gleich gewichtet sind). Berechnet wird sie als Summe der Fertilitätsziffern für einjährige Altersgruppen (Summe der Quotienten aus den Lebendgeborenen nach einjährigen Altersgruppen der Mütter und den Frauen gleichen Alters).

Lebenserwartung: Die für eine bestimmte Beobachtungsperiode wie z.B. ein Kalenderjahr berechnete Lebenserwartung bei der Geburt gibt an, wie viele Jahre ein neugeborenes Kind im Durchschnitt leben würde, wenn im Laufe seines Lebens stets dieselben altersspezifischen Sterblichkeitsverhältnisse (genauer: Sterbeziffern für einzelne Altersjahre) herrschen würden wie in dem betreffenden Kalenderjahr. Sie eignet sich als Prognosewert für die Lebensdauer eines Neugeborenen nur unter der unrealistischen Annahme, dass in den nachfolgenden hundert Kalenderjahren die altersspezifischen Sterbeziffern unverändert bleiben. Entsprechendes gilt für die fernere Lebenserwartung einer Person im Alter von genau 1 Jahr, 2 Jahren etc.). In erster Linie stellt sie einen zusammenfassenden Indikator der altersspezifischen Sterbeziffern eines Kalenderjahres dar. Berechnet wird sie als Summe der stationären Bevölkerung einer Sterbetafel, normiert auf den Umfang des Ausgangsbestandes an Lebendgeborenen (also: dividiert durch 100.000). Als Mittelwert dient das arithmetische Mittel.

Nettoreproduktionsrate (NRR): Sie gibt an, wie viele lebendgeborene Töchter eine Frau zur Welt bringen würde, wenn im Laufe ihres Lebens dieselben altersspezifischen Fertilitäts- und Sterblichkeitsverhältnisse herrschen würden wie in dem betreffenden Kalenderjahr. Sie unterscheidet sich von der Bruttoreproduktionsrate (BRR) dadurch, dass hier auch die weibliche Sterblichkeit vom Zeitpunkt der Geburt bis in die einzelnen Altersjahre der Mütter berücksichtigt wird. Sie gibt an, wieweit eine Müttergeneration durch Töchter ersetzt wird, wenn die in der Berichtsperiode herrschenden Fertilitäts- und Sterblichkeitsverhältnisse fort dauern würden; der Wert 1 bedeutet dabei vollen Ersatz, d.h. im wesentlichen, dass die Fertilität ausreicht, um die Elterngeneration vollständig durch ihre Kinder zu ersetzen; ein Wert von 0,7 bedeutet beispielsweise, dass es zu einer 30-prozentigen Schrumpfung der Elterngeneration kommen würde usw.

Berechnet wird die NRR als Summe der Produkte aus a) den Quotienten aus den Lebendgeborenen nach einjährigen Altersgruppen der Mütter und den Frauen gleichen Alters und b) der gleichaltrigen stationären weiblichen Bevölkerung (welche auf den Umfang der Ausgangskohorte, hier 100.000, normiert wurde); diese Produktsumme wird dann mit einem von vorneherein festgelegten Anteil von Mädchengeburten an den Lebendgeborenen insgesamt multipliziert (dieser Anteil ist ein Durchschnitt der letzten hundert Jahre, und entspricht einer Sexualproportion der Lebendgeborenen von 1.057 Knaben auf 1.000 Mädchen; die Fixierung dieses Anteils wurde vorgenommen, um die jährlichen Zufallsschwankungen nicht auf die NRR durchschlagen zu lassen). Die normierte stationäre weibliche Bevölkerung, welche die Überlebenswahrscheinlichkeit der neugeborenen Mädchen bis zum jeweiligen Fertilitätsalter der Mütter darstellt, entstammt einer für das betreffende Kalenderjahr in ausführlicher Form berechneten rohen allgemeinen Sterbetafel.

Sexualproportion: Männliche auf 1.000 weibliche Personen.
